1 Probability and random variables

- **Probability**: S sample space (all possible states of the system), $F \subset \mathcal{P}(S)$ a σ-algebra, $P : F \to \mathbb{R}$ a measure, such that $P(S) = 1$.
- **Random variable**: $X : S \to \mathbb{R}$, such that preimages of open sets are in F (i.e. has a well defined probability).
- **Cumulative distribution function** of random variable: $F_X(t) = P(X \leq t)$.
- **Probability distribution** of random variable: g such that $F_X(t) = \sum_{x \leq t, x \in C} g(x)$.
- **Probability density function**: f such that $F_X(t) = \int_{-\infty}^{t} f(s)ds$.
- Two random variables have the **same distribution** if they have the same cdf.

Example: **uniform distribution**:

- S a finite interval $[a, b]$
- F: Set of Borel sets on S (sets with a well defined "length")
- P: Borel measure ("length") divided by $b - a$
- $X = id$.

1.1 Expectation of random variables and their functions

- X is a random variable, the **expectation** of X is $E[X] = \int_S X dP$.
- The **variance** of X is $E[(X - E[X])^2]$.
- The k-th **moment** of X is $E[X^k]$.
- The **moment generating function** of X is $E[e^{Xt}]$ (two sided Laplace transform)
- The **characteristic function** of X is $E[e^{itX}]$ (Fourier transform)

Since expectation is defined via integration, one can use the properties of integration to prove statements regarding expectation.

Example: **Chebyshev's theorem**: $E[X] = 0$, $E[X^2] = 1$, then $P(|X| < k) \geq 1 - \frac{1}{k^2}$.
Proof:

$$1 = E[X^2] = \int_S X^2 dP \geq k^2 \int_{|X| \geq k} 1 dP = k^2(1 - P(|X| < k))$$

Example: If X has p.d.f. f_X, then $E[g(X)] = \int_{-\infty}^{\infty} g f_x dt$. We prove it when $g(X)$ is bounded via Fubini's theorem:

$$E[g(X)] = \int_S g(X) dP$$
$$= \int_{g(X)\geq 0} \int_0^{g(X)} 1 dy dP - \int_{g(X)<0} \int_{g(X)}^0 1 dy dP$$
$$= \int_0^{\infty} \int_{g^{-1}([y,\infty])} f_X(t) dt dy - \int_{-\infty}^0 \int_{g^{-1}([-\infty,y])} f_X(t) dt dy$$
$$= \int_{-\infty}^{\infty} g f_x dt$$

There is a multivariate version of this formula, and one can also write down $E[g(X)]$ when only the c.d.f. of X is known (via Fubini's theorem or integration by parts).

Can you write down a random variable with neither probability distribution nor p.d.f.?

Can you write down a random variable with no expectation?

1.2 Independence and conditional probability for random events

- $A, B \in F$ are **independent** iff $P(A \cap B) = P(A)P(B)$.
- If $P(B) \neq 0$, $P(A \cap B) = P(B)P(A|B)$. Here $P(A|B)$ is the **conditional probability** of A when B is known to happen.

1.3 Joint distribution, marginal distribution, conditional distribution

1.3.1 Joint distribution

- X and Y are two random variables. The **joint cumulative distribution function** is $F(s,t) = P(X \leq s, Y \leq t)$.
- If $F(s,t) = \sum_{(x,y)\in C, x\leq s, y\leq t} g(s,t)$, we call g the **joint probability distribution**.
- If $F(s,t) = \int_{(-\infty,s]\times(-\infty,t]} f(x,y) dx dy$ we call f the **joint probability density function**.
- X and Y are called independent iff the joint c.d.f. is $F(x,y) = F_X(x)F_Y(y)$.
- The **covariance** between X and Y is $E[(X - E[X])(Y - E[Y])]$

Example: X and Y are two independent random variable with uniform distribution on $[0, 1]$. What is the joint distribution function of X and Y? How about $max(X, Y)$ and $min(X, Y)$? What are their covariances?

1.3.2 Marginal distribution

Knowing the joint c.d.f. of X and Y, the c.d.f. of X or Y are called the **marginal cumulative distribution function**, their p.d. or p.d.f. the **marginal p.d.** or **marginal p.d.f**.

1.3.3 Conditional distribution

- If A is a set such that $P(Y \in A) > 0$, then the **conditional cumulative distribution function** of X is $F_{X|Y \in A}(t) = P(X \leq t|Y \in A) = P(X \leq t \cap Y \in A)/P(Y \in A)$. The **conditional p.d.f.**, **conditional p.d.** and **conditional expectation** are defined similarly.

- If $P(Y \in A) = 0$ there isn't a definition of conditional distribution that works in all cases. For example, if X, Y has joint p.d.f. $f_{X,Y}$, and the marginal p.d.f. of Y, denoted as $f_Y(y) = \int_{\mathbb{R}} f_{X,Y}(x, y)dx$, exists and is non zero at y_0, then the conditional p.d.f. at $Y = y_0$ is defined as $f_{X|Y=y_0} = f_{X,Y}(x, y_0)/f_Y(y_0)$. The conditional c.d.f. is its integral.

Remark: The definition of conditional distribution for the case $P(Y \in A) = 0$ depends on Y and not just $Y^{-1}(A)$. For example, if $Z = Ye^X$, $f_{X|Y=0} \neq f_{X|Z=0}$.

Example: X is a random variable with uniform distribution on $[0, 1]$, $P(Y = 1|X = p) = p$ (i.e. $P(Y = 1|X \in A) = \int_A pdF_x(p)$), $P(Y = 0|X = p) = 1 - p$. Find the conditional distribution of X when $Y = 1$.

When there are N random variables, $N \geq 3$, the joint/marginal/conditional distributions can be defined analogously.
